Summary

In this milestone, we moved from the console to a real GUI using Windows Forms, which makes the game actually playable with a mouse. The biggest thing we learned was Event-Driven Programming, which just means the code sits there and waits for an event—like me clicking a button instead of running straight through from start to finish. We also got practice with controls like Buttons and Panels, dynamically creating a grid of them in the code to match our board size. It really showed why we kept our logic separate in the BLL earlier, because it was super easy to just plug that existing code into the new forms to make the buttons change colors and show numbers.
